(54) Title: PROCESS FOR CONTROLLING SCARAB PESTS WITH <i>BACILLUS THURINGIENSIS</i> ISOLATES (57) Abstract Certain isolates of <i>Bacillus thuringiensis</i> (B.t.) have been found to have activity against scarab pests. These isolates are de- signated B.t. PS86B1, B.t. PS43F and B.t. PS50C. These isolates, or transformed hosts containing the gene expressing a scarab-ac- tive toxin obtained from the isolates, can be used to control scarab-active pests, e.g., masked chafer, <i>Cyclocephala</i> sp., June beetle, <i>Cotinis</i> sp., northern masked chafer, <i>Cyclocephala borealis</i> , Japanese beetle, <i>Popillia japonica</i> , and Pasadena masked chafer, <i>Cyclocephala pasadenae</i> , in various environments.

DESCRIPTIONPROCESS FOR CONTROLLING SCARAB PESTS WITH
BACILLUS THURINGIENSIS ISOLATES

5

Cross-Reference to a Related Application

This is a continuation-in-part of co-pending application Serial No. 07/828,430, filed January 30, 1992, which is a continuation-in-part of co-pending application Serial No. 07/808,316, filed on December 16, 1991, now abandoned.

10

Background of the Invention

15

The soil microbe *Bacillus thuringiensis* (*B.t.*) is a Gram-positive, spore-forming bacterium characterized by parasporal crystalline protein inclusions. These often appear microscopically as distinctively shaped crystals. The proteins can be highly toxic to pests and specific in their activity. Certain *B.t.* toxin genes have been isolated and sequenced, and recombinant DNA-based *B.t.* products produced and approved. In addition, with the use of genetic engineering techniques, new approaches for delivering *B.t.* endotoxins to agricultural environments are under development, including the use of plants genetically engineered with endotoxin genes for insect resistance and the use of stabilized intact microbial cells as *B.t.* endotoxin delivery vehicles (Gaertner, F.H., L. Kim [1988] *TIBTECH* 6:S4-S7). Thus, isolated *B.t.* endotoxin genes are becoming commercially valuable.

20

25

Over the past 30 years, commercial use of *B.t.* pesticides has been largely restricted to a narrow range of lepidopteran (caterpillar) pests. Preparations of the spores and crystals of *B. thuringiensis* subsp. *kurstaki* have been used for many years as commercial insecticides for lepidopteran pests. For example, *B. thuringiensis* var. *kurstaki* HD-1 produces a crystal called a delta endotoxin which is toxic to the larvae of a number of lepidopteran insects.

30

In recent years, however, investigators have discovered *B.t.* pesticides with specificities for a much broader range of pests. For example, other species of *B.t.*, namely *israelensis* and *san diego* (a.k.a. *B.t. tenebrionis*, a.k.a. M-7), have been used commercially to control insects of the orders Diptera and Coleoptera, respectively

(Gaertner, F.H. [1989] "Cellular Delivery Systems for Insecticidal Proteins: Living and Non-Living Microorganisms," in *Controlled Delivery of Crop Protection Agents*, R.M. Wilkins, ed., Taylor and Francis, New York and London, 1990, pp. 245-255). See also Couch, T.L. (1980) "Mosquito Pathogenicity of *Bacillus thuringiensis* var. *israelensis*," *Developments in Industrial Microbiology* 22:61-76; Beegle, C.C., (1978) "Use of Entomogenous Bacteria in Agroecosystems," *Developments in Industrial Microbiology* 20:97-104. Krieg, A., A.M. Huger, G.A. Langenbruch, W. Schnetter (1983) *Z. ang. Ent.* 96:500-508, describe a *B.t.* isolate named *Bacillus thuringiensis* var. *tenebrionis*, which is reportedly active against two beetles in the order Coleoptera. These are the Colorado potato beetle, *Leptinotarsa decemlineata*, and *Agelastica alni*.

Recently, new subspecies of *B.t.* have been identified, and genes responsible for active δ -endotoxin proteins have been isolated (Höfte, H., H.R. Whiteley [1989] *Microbiological Reviews* 52(2):242-255). Höfte and Whiteley classified *B.t.* crystal protein genes into 4 major classes. The classes were CryI (Lepidoptera-specific), CryII (Lepidoptera- and Diptera-specific), CryIII (Coleoptera-specific), and CryIV (Diptera-specific). The discovery of strains specifically toxic to other pests has been reported. (Feitelson, J.S., J. Payne, L. Kim [1992] *Bio/Technology* 10:271-275).

The cloning and expression of a *B.t.* crystal protein gene in *Escherichia coli* has been described in the published literature (Schnepf, H.E., H.R. Whiteley [1981] *Proc. Natl. Acad. Sci. USA* 78:2893-2897). U.S. Patent 4,448,885 and U.S. Patent 4,467,036 both disclose the expression of *B.t.* crystal protein in *E. coli*. U.S. Patents 4,797,276 and 4,853,331 disclose *B. thuringiensis* strain *san diego* (a.k.a. *B.t. tenebrionis*, a.k.a. M-7) which can be used to control coleopteran pests in various environments. U.S. Patent No. 5,151,363 discloses certain isolates of *B.t.* which have activity against nematodes. Many other patents have issued for new *B.t.* isolates and new uses of *B.t.* isolates. The discovery of new *B.t.* isolates and new uses of known *B.t.* isolates remains an empirical, unpredictable art.

Insects in the family Scarabaeidae (scarabs) constitute a serious pest control problem, especially when destructive larval stage insects infest high value turf found in golf courses, playing fields and lawns. The larvae of many species also attack grains, tuberous crops, and ornamentals. Larvae are called "white grubs" or "chafer grubs" and can be found in decaying organic matter (rotting leaves, manure, etc.) or

2-10 cm. deep in soil where they consume the plant roots. In turf infested areas there can be as many as 30 grubs per square foot. The damage caused by an infestation becomes most apparent in the fall when the third instar grubs are feeding. Adult beetles of some scarab species will feed on a wide variety of vegetative host, damaging foliage, fruit and flowers of woody and herbaceous plants. In the U.S. and Europe, populations of larvae and adults have developed resistance to chemical insecticides such as the organochlorines and DDT.

Several scarab pests are of economic importance. Particularly important pests in the U.S., especially east of the Rockies, but also in the Western States, are the masked chafers, *Cyclocephala* sp. In the east, the northern masked chafer, *C. borealis*, and the southern masked chafer, *C. immaculata*, are common pests, while, in California, *C. hirta* and *C. pasadenae* are present. Also, in the U.S., especially in the area east of the rockies, infestations of Japanese beetles *Popillia* sp., May or June beetles *Phyllophaga* sp., black turfgrass beetles *Ataenius* sp., European chafers *Rhizotrogus* sp., tend to necessitate the greatest amount of insecticide treatments. Other important scarab pests in the U.S. can be quite damaging but localized such as with Oriental beetles *Anomala* sp., hoplia chafers *Hoplia* sp., green June beetle *Cotinis* sp., and Asiatic garden beetles *Maladera* sp. Several scarabs not present in the U.S. are of economic importance in Europe, including rose chafers *Cetonia* sp., cockchafers *Melolontha* sp., flower beetles *Adoretus* sp., and garden chafers *Phyllopertha* sp. The green June beetles, *Cotinis* sp., can cause serious damage where populations become abundant. The adults are attracted to ripening fruit and will devour figs, peaches and other thin skinned fruit while on the tree. Larvae are attracted to decaying organic matter and most commonly become pests in turf or fields which have been fertilized with manure. The feeding and tunnelling of the large larvae can become disruptive. The eastern green June beetle *Cotinis nitida* is present in the mid-western and eastern states, while the green June beetle *C. mutabilis* occurs in many of the western states.

Brief Summary of the Invention

The subject invention concerns novel materials and methods for controlling scarab pests. The materials and methods of the subject invention result from the unexpected discovery that certain *B.t.* isolates have activity against these pests.

More specifically, the methods of the subject invention use *B.t.* microbes, or variants thereof, and/or their toxins, to control scarab pests. Specific *B.t.* microbes useful according to the invention are *B.t.* PS86B1, *B.t.* PS43F, and *B.t.* PS50C. Further, the subject invention also includes the use of variants of the exemplified *B.t.* isolates which have substantially the same scarab-active properties as the specifically exemplified *B.t.* isolates. Such variants would include, for example, mutants. Procedures for making mutants are well known in the microbiological art. Ultraviolet light and nitrosoguanidine are used extensively toward this end.

The subject invention also includes the use of genes from the *B.t.* isolates of the invention which genes encode the scarab-active toxins.

Still further, the invention also includes the treatment of substantially intact *B.t.* cells, or recombinant cells containing the genes of the invention, to prolong the scarab activity when the substantially intact cells are applied to the environment of a target pest. Such treatment can be by chemical or physical means, or a combination of chemical and physical means, so long as the technique does not deleteriously affect the properties of the pesticide, nor diminish the cellular capability in protecting the pesticide. The treated cell acts as a protective coating for the pesticidal toxin. The toxin becomes available to act as such upon ingestion by a target insect.

Finally, the subject invention further concerns plants which have been transformed with genes encoding scarab-active toxins.

Brief Description of the Sequences

SEQ ID NO. 1 is the nucleotide sequence (open reading frame only) of the gene designated 50C(a).

SEQ ID NO. 2 is the predicted amino acid sequence of the toxin 50C(a).

5 SEQ ID NO. 3 is the nucleotide sequence (open reading frame only) of the gene designated 50C(b).

SEQ ID NO. 4 is the predicted amino acid sequence of the toxin 50C(b).

SEQ ID NO. 5 is the composite nucleotide sequence and deduced amino acid sequence of the gene designated 43F.

10 SEQ ID NO. 6 is the predicted amino acid sequence of the toxin 43F.

Detailed Disclosure of the Invention

The subject invention concerns the use of selected strains of *Bacillus thuringiensis* for the control of scarab pests.

15 Specific *Bacillus thuringiensis* isolates useful according to the subject invention have the following characteristics in their biologically pure form:

Characteristics of *B.t.* PS50C

Colony morphology--Large colony, dull surface, typical *B.t.*

20 Vegetative cell morphology--typical *B.t.*

Culture methods--typical for *B.t.*

Flagellar serotyping--PS50C belongs to serotype 18, kumamotoensis.

Crystal morphology--a sphere.

25 RFLP analysis--Southern hybridization of total DNA distinguishes *B.t.* PS50C from *B.t.s.d.* and other *B.t.* isolates.

Alkali-soluble proteins--SDS polyacrylamide gel electrophoresis (SDS-PAGE) shows a 130 kDa doublet protein.

A comparison of the characteristics of *B. thuringiensis* PS50C (*B.t.* PS50C) to the characteristics of the known *B.t.* strains *B. thuringiensis* var. *san diego* (*B.t.s.d.*),
30 *B. thuringiensis* PS86B1 (NRRL B-18299), and *B. thuringiensis* var. *kurstaki* (HD-1) is shown in Table 1.

Table 1. Comparison of *B.t.* PS50C, *B.t.* PS86B1, *B.t.s.d.*, and *B.t.* HD-1

	<i>B.t.</i> PS50C	<i>B.t.s.d.</i>	<i>B.t.</i> PS86B1	<i>B.t.</i> HD-1
Serovar	kumamotoensis	morrisoni	tolworthi	kurstaki
Type of inclusion	sphere	square wafer	flat, pointed ellipse, plus sm. inclusions	Bipyramid
Size of alkali-soluble proteins by SDS-PAGE	130 kDa doublet	72,000 64,000	75,000 68,000 61,000	130,000 68,000
Host range	Coleoptera	Coleoptera	Coleoptera	Lepidoptera

B.t. isolates useful according to the subject invention have been deposited. Also deposited are recombinant microbes comprising the *B.t.* genes of interest.

<u>Culture</u>	<u>Accession Number</u>	<u>Deposit Date</u>
<i>Bacillus thuringiensis</i> PS86B1	NRRL B-18299	February 3, 1988
<i>Bacillus thuringiensis</i> PS43F	NRRL B-18298	February 3, 1988
<i>E. coli</i> XL1-Blue(pM1,98-4)	NRRL B-18291	January 15, 1988

<i>E. coli</i> NM522(pMYC1638)	NRRL B-18751	January 11, 1991

The cultures are on deposit in the permanent collection of the Northern Research Laboratory, U.S. Department of Agriculture, Peoria, IL, USA.

The subject cultures have been deposited under conditions that assure that access to the cultures will be available during the pendency of this patent application to one determined by the Commissioner of Patents and Trademarks to be entitled thereto under 37 CFR 1.14 and 35 USC 122. The deposits are available as required by foreign patent laws in countries wherein counterparts of the subject application, or its progeny, are filed. However, it should be understood that the availability of a deposit does not constitute a license to practice the subject invention in derogation of patent rights granted by governmental action.

Further, the subject culture deposits will be stored and made available to the public in accord with the provisions of the Budapest Treaty for the Deposit of

Microorganisms, i.e., they will be stored with all the care necessary to keep them viable and uncontaminated for a period of at least five years after the most recent request for the furnishing of a sample of the deposit, and in any case, for a period of at least 30 (thirty) years after the date of deposit or for the enforceable life of any patent which may issue disclosing the cultures. The depositor acknowledges the duty to replace the deposits should the depository be unable to furnish a sample when requested, due to the condition of the deposit(s). All restrictions on the availability to the public of the subject culture deposits will be irrevocably removed upon the granting of a patent disclosing them.

Genes and toxins. The genes and toxins according to the subject invention include not only the full length sequences disclosed herein but also fragments of these sequences, or fusion proteins, which retain the characteristic pesticidal activity of the toxins specifically exemplified herein.

It should be apparent to a person skilled in this art that genes coding for scarab-active toxins can be identified and obtained through several means. The specific genes exemplified herein may be obtained from the isolates deposited at a culture depository as described above. These genes, or portions or variants thereof, may also be constructed synthetically, for example, by use of a gene machine. As used herein, the terms "variants" or "variations" of genes refer to nucleotide sequences which code for the same toxins or which code for equivalent toxins having scarab activity. Variations of these genes may be readily constructed using standard techniques for making point mutations. Also, fragments of these genes can be made using commercially available exonucleases or endonucleases according to standard procedures. For example, enzymes such as *Bal31* or site-directed mutagenesis can be used to systematically cut off nucleotides from the ends of these genes. Also, genes which code for active fragments may be obtained using a variety of other restriction enzymes. Proteases may be used to directly obtain active fragments of these toxins.

Equivalent toxins and/or genes encoding these equivalent toxins can also be located from *B.t.* isolates and/or DNA libraries using the teachings provided herein. These "equivalent" toxins and genes are also referred to herein as "variant" toxins or genes. There are a number of methods for obtaining the pesticidal toxins of the instant invention. For example, antibodies to the pesticidal toxins disclosed and

claimed herein can be used to identify and isolate other toxins from a mixture of proteins. Specifically, antibodies may be raised to the portions of the toxins which are most constant and most distinct from other *B.t.* toxins. These antibodies can then be used to specifically identify equivalent toxins with the characteristic activity by immunoprecipitation, enzyme linked immunoassay (ELISA), or Western blotting. Antibodies to the toxins disclosed herein, or to equivalent toxins, or fragments of these toxins, can readily be prepared using standard procedures in this art. The genes coding for these toxins can then be obtained from the microorganism.

A further method for identifying the toxins and genes of the subject invention is through the use of oligonucleotide probes. These probes are nucleotide sequences having a detectable label. As is well known in the art, if the probe molecule and nucleic acid sample hybridize by forming a strong bond between the two molecules, it can be reasonably assumed that the probe and sample have substantial homology. The probe's detectable label provides a means for determining in a known manner whether hybridization has occurred. Such a probe analysis provides a rapid method for identifying toxin-encoding genes of the subject invention. The nucleotide segments which are used as probes according to the invention can be synthesized by use of DNA synthesizers using standard procedures.

Fragments and mutations of the exemplified toxins, which retain the pesticidal activity of the exemplified toxins, would be within the scope of the subject invention, as would genes which encode such fragments and mutants. Also, because of the redundancy of the genetic code, a variety of different DNA sequences can encode the amino acid sequences disclosed herein. It is well within the skill of a person trained in the art to create these alternative DNA sequences encoding the same, or essentially the same, toxins. These variant DNA sequences are within the scope of the subject invention. As used herein, reference to "essentially the same" sequence refers to sequences which have amino acid substitutions, deletions, additions, or insertions which do not materially affect pesticidal activity. Fragments retaining scarab activity are also included in this definition. As used herein, the phrase "scarab activity" includes activity against scarab larvae as well as other stages of development.

Toxins of the subject invention are specifically exemplified herein by the toxins encoded by the genes designated 50C(a), 50C(b), and 43F. Since these toxins are

merely exemplary of the toxins of the subject invention, it should be readily apparent that the subject invention further comprises variant toxins (and nucleotide sequences coding for variant toxins) having the same or essentially the same biological activity against scarab pests of the exemplified toxins. These equivalent toxins will have amino acid homology with a toxin of the subject invention. This amino acid homology will typically be greater than 75%, preferably be greater than 90%, and most preferably be greater than 95%. The amino acid homology will be highest in certain critical regions of the toxins which account for biological activity or are involved in the determination of three-dimensional configuration which ultimately is responsible for the biological activity. In this regard, certain amino acid substitutions are acceptable and can be expected if these substitutions are in regions which are not critical to activity or are conservative amino acid substitutions which do not affect the three-dimensional configuration of the molecule. For example, amino acids may be placed in the following classes: non-polar, uncharged polar, basic, and acidic. Conservative substitutions whereby an amino acid of one class is replaced with another amino acid of the same type fall within the scope of the subject invention so long as the substitution does not materially alter the biological activity of the compound. Table 2 provides a listing of examples of amino acids belonging to each class.

Table 2

Class of Amino Acid	Examples of Amino Acids
Nonpolar	Ala, Val, Leu, Ile, Pro, Met, Phe, Trp
Uncharged Polar	Gly, Ser, Thr, Cys, Tyr, Asn, Gln
Acidic	Asp, Glu
Basic	Lys, Arg, His

In some instances, non-conservative substitutions can also be made. The critical factor is that these substitutions must not significantly detract from the biological activity of the toxin.

The toxins of the subject invention can also be characterized in terms of the shape and location of toxin inclusions, which are described above.

Recombinant hosts. The toxin-encoding genes harbored by the isolates of the subject invention can be introduced into a wide variety of microbial or plant hosts. Expression of the toxin gene results, directly or indirectly, in the intracellular production and maintenance of the pesticide. With suitable microbial hosts, e.g., *Pseudomonas*, the microbes can be applied to the situs of scarab pests where they will proliferate and be ingested by the pest. The result is a control of this pest. Alternatively, the microbe hosting the toxin gene can be treated under conditions that prolong the activity of the toxin produced in the cell. The treated cell then can be applied to the environment of the target pest. The resulting product retains the toxicity of the *B.t.* toxin.

Where the *B.t.* toxin gene is introduced via a suitable vector into a microbial host, and said host is applied to the environment in a living state, it is essential that certain host microbes be used. Microorganism hosts are selected which are known to occupy the soil. These microorganisms are selected so as to be capable of successfully competing in the soil with the wild-type microorganisms, provide for stable maintenance and expression of the gene expressing the polypeptide pesticide, and, desirably, provide for improved protection of the pesticide from environmental degradation and inactivation.

A large number of microorganisms are known to inhabit the rhizosphere (the soil surrounding plant roots). These microorganisms include bacteria, algae, and fungi. Of particular interest are microorganisms, such as bacteria, e.g., genera *Bacillus*, *Pseudomonas*, *Erwinia*, *Serratia*, *Klebsiella*, *Xanthomonas*, *Streptomyces*, *Rhizobium*, *Rhodopseudomonas*, *Methylophilus*, *Agrobacterium*, *Acetobacter*, *Lactobacillus*, *Arthrobacter*, *Azotobacter*, *Leuconostoc*, *Alcaligenes* and *Clostridium*; fungi, particularly yeast, e.g., genera *Saccharomyces*, *Cryptococcus*, *Khuyveromyces*, *Sporobolomyces*, *Rhodotorula*, and *Aureobasidium*; microalgae, e.g., families *Cyanophyceae*, *Prochlorophyceae*, *Rhodophyceae*, *Dinophyceae*, *Chrysophyceae*, *Prymnesiophyceae*, *Xanthophyceae*, *Raphidophyceae*, *Bacillariophyceae*, *Eustigmatophyceae*, *Cryptophyceae*, *Euglenophyceae*, *Prasinophyceae*, and *Chlorophyceae*. Of particular interest are such phytosphere bacterial species as

Pseudomonas syringae, *Pseudomonas fluorescens*, *Serratia marcescens*, *Acetobacter xylinum*, *Agrobacterium tumefaciens*, *Rhodopseudomonas spheroides*, *Xanthomonas campestris*, *Rhizobium melioli*, *Alcaligenes entrophus*, and *Azotobacter vinlandii*; and phytosphere yeast species such as *Rhodotorula rubra*, *R. glutinis*, *R. marina*, *R. aurantiaca*, *Cryptococcus albidus*, *C. diffluens*, *C. laurentii*, *Saccharomyces rosei*, *S. pretoriensis*, *S. cerevisiae*, *Sporobolomyces roseus*, *S. odor*, *Kluyveromyces veronae*, and *Aureobasidium pollulans*. Of particular interest are the pigmented microorganisms.

A wide variety of ways are available for introducing a *B.t.* gene encoding a toxin into a microorganism host under conditions which allow for stable maintenance and expression of the gene. These methods are well known to those skilled in the art and are described, for example, in United States Patent No. 5,135,867, which is incorporated herein by reference.

Treatment of cells. As mentioned above, *B.t.* or recombinant cells expressing a *B.t.* toxin can be treated to prolong activity in the environment. Suitable host cells, where the pesticide-containing cells will be treated to prolong the activity of the toxin in the cell when the then treated cell is applied to the environment of target pest(s), may include either prokaryotes or eukaryotes, normally being limited to those cells which do not produce substances toxic to higher organisms, such as mammals. However, organisms which produce substances toxic to higher organisms could be used, where the toxin is unstable or the level of application sufficiently low as to avoid any possibility of toxicity to a mammalian host. As hosts, of particular interest will be the prokaryotes and the lower eukaryotes, such as fungi.

The cell will usually be intact and be substantially in the proliferative form when treated, rather than in a spore form, although in some instances spores may be employed.

Treatment of the microbial cell, e.g., a microbe containing the *B.t.* toxin gene, can be by chemical or physical means, or by a combination of chemical and/or physical means, so long as the technique does not deleteriously affect the properties of the toxin, nor diminish the cellular capability in protecting the toxin. Examples of chemical reagents are halogenating agents, particularly halogens of atomic no. 17-80. More particularly, iodine can be used under mild conditions and for sufficient time to

achieve the desired results. Other suitable techniques include treatment with aldehydes, such as formaldehyde and glutaraldehyde; anti-infectives, such as zephiran chloride and cetylpyridinium chloride; alcohols, such as isopropyl and ethanol; various histologic fixatives, such as Lugol iodine, Bouin's fixative, and Helly's fixative (See: Humason, Gretchen L., *Animal Tissue Techniques*, W.H. Freeman and Company, 1967); or a combination of physical (heat) and chemical agents that preserve and prolong the activity of the toxin produced in the cell when the cell is administered to the host animal. Examples of physical means are short wavelength radiation such as gamma-radiation and X-radiation, freezing, UV irradiation, lyophilization, and the like.

The cells generally will have enhanced structural stability which will enhance resistance to environmental conditions. Where the pesticide is in a proform, the method of inactivation should be selected so as not to inhibit processing of the proform to the mature form of the pesticide by the target pest pathogen. For example, formaldehyde will crosslink proteins and could inhibit processing of the proform of a polypeptide pesticide. The method of inactivation or killing retains at least a substantial portion of the bio-availability or bioactivity of the toxin.

Characteristics of particular interest in selecting a host cell for purposes of production include ease of introducing the *B.t.* gene into the host, availability of expression systems, efficiency of expression, stability of the pesticide in the host, and the presence of auxiliary genetic capabilities. Characteristics of interest for use as a pesticide microcapsule include protective qualities for the pesticide, such as thick cell walls, pigmentation, and intracellular packaging or formation of inclusion bodies; survival in aqueous environments; lack of mammalian toxicity; attractiveness to pests for ingestion; ease of killing and fixing without damage to the toxin; and the like. Other considerations include ease of formulation and handling, economics, storage stability, and the like.

Growth of cells. The cellular host containing the *B.t.* insecticidal gene may be grown in any convenient nutrient medium, where the DNA construct provides a selective advantage, providing for a selective medium so that substantially all or all of the cells retain the *B.t.* gene. These cells may then be harvested in accordance with conventional ways. Alternatively, the cells can be treated prior to harvesting.

The *B.t.* cells of the invention can be cultured using standard art media and fermentation techniques. Upon completion of the fermentation cycle the bacteria can be harvested by first separating the *B.t.* spores and crystals from the fermentation broth by means well known in the art. The recovered *B.t.* spores and crystals can be formulated into a wettable powder, liquid concentrate, granules or other formulations by the addition of surfactants, dispersants, inert carriers, and other components to facilitate handling and application for particular target pests. These formulations and application procedures are all well known in the art.

Formulations. Formulated bait granules containing an attractant and spores and crystals of the *B.t.* isolates, or recombinant microbes comprising the gene(s) obtainable from the *B.t.* isolates disclosed herein, can be applied to the soil. Formulated product can also be applied as a seed-coating or root treatment or total plant treatment at later stages of the crop cycle.

As would be appreciated by a person skilled in the art, the pesticidal concentration will vary widely depending upon the nature of the particular formulation, particularly whether it is a concentrate or to be used directly. The pesticide will be present in at least 1% by weight and may be 100% by weight. The dry formulations will have from about 1-95% by weight of the pesticide while the liquid formulations will generally be from about 1-60% by weight of the solids in the liquid phase. The formulations will generally have from about 10^2 to about 10^4 cells/mg. These formulations will be administered at about 50 mg (liquid or dry) to 1 kg or more per hectare.

The formulations can be applied to the environment of the scarab, e.g., soil, by spraying, dusting, sprinkling, or the like.

The *B.t.* pesticide of the invention can be applied to the soil to control scarab larvae as follows:

- a granule to the soil
- a granule mixed with sand, which fills holes during aeration of turf
- a granule with a sub-surface applicator upon re-seeding in turf
- a spray to the soil (soil drench)
- a spray following aeration
- a spray applied with sub-surface applicator

— combined with a water holding polymer placed in soil with a sub-~~surface~~ applicator.

B.t. pesticidal treatment for adult scarab pests can be done as follows:

- 5
- granules with attractant, dispersed in area where beetles are flying
 - attractant bait where beetles can congregate to feed
 - as a foliar spray to host plant.

10 Mutants. Mutants of the novel isolates of the invention can be made by procedures well known in the art. For example, an asporogenous mutant can be obtained through ethylmethane sulfonate (EMS) mutagenesis of a novel isolate. The mutants can be made using ultraviolet light and nitrosoguanidine by procedures well known in the art.

15 A smaller percentage of the asporogenous mutants will remain intact and not lyse for extended fermentation periods; these strains are designated lysis minus (—). Lysis minus strains can be identified by screening asporogenous mutants in shake flask media and selecting those mutants that are still intact and contain toxin crystals at the end of the fermentation. Lysis minus strains are suitable for a cell fixation process that will yield a protected, encapsulated toxin protein.

20 To prepare a phage resistant variant of said asporogenous mutant, an aliquot of the phage lysate is spread onto nutrient agar and allowed to dry. An aliquot of the phage sensitive bacterial strain is then plated directly over the dried lysate and allowed to dry. The plates are incubated at 30RC. The plates are incubated for 2 days and, at that time, numerous colonies could be seen growing on the agar. Some of these

25 colonies are picked and subcultured onto nutrient agar plates. These apparent resistant cultures are tested for resistance by cross streaking with the phage lysate. A line of the phage lysate is streaked on the plate and allowed to dry. The presumptive resistant cultures are then streaked across the phage line. Resistant bacterial cultures show no lysis anywhere in the streak across the phage line after overnight incubation

30 at 30RC. The resistance to phage is then reconfirmed by plating a lawn of the resistant culture onto a nutrient agar plate. The sensitive strain is also plated in the same manner to serve as the positive control. After drying, a drop of the phage lysate

is plated in the center of the plate and allowed to dry. Resistant cultures showed no lysis in the area where the phage lysate has been placed after incubation at 30RC for 24 hours.

- 5 Following are examples which illustrate procedures, including the best mode, for practicing the invention. These examples should not be construed as limiting. All percentages are by weight and all solvent mixture proportions are by volume unless otherwise noted.

10 Example 1 — Culturing *B.t.* Isolates and Transformed Hosts

A subculture of the *B.t.* isolates and transformed hosts of the invention can be used to inoculate the following medium, a peptone, glucose, salts medium.

	Bacto Peptone	7.50 g/l
	Glucose	1.00 g/l
15	KH ₂ PO ₄	3.40 g/l
	K ₂ HPO ₄	4.35 g/l
	Salt Solution	5.00 ml/l
	CaCl ₂ Solution	5.00 ml/l
	Salts Solution (100 ml)	
20	MgSO ₄ ·7H ₂ O	2.46 g
	MnSO ₄ ·H ₂ O	0.04 g
	ZnSO ₄ ·7H ₂ O	0.28 g
	FeSO ₄ ·7H ₂ O	0.40 g
	CaCl ₂ Solution (100 ml)	
25	CaCl ₂ ·2H ₂ O	3.66 g

pH 7.2

- 30 The salts solution and CaCl₂ solution are filter-sterilized and added to the autoclaved and cooked broth at the time of inoculation. Flasks are incubated at 30RC on a rotary shaker at 200 rpm for 64 hours.

The above procedure can be readily scaled up to large fermentors by procedures well known in the art.

The *B.t.* spores and crystals, obtained in the above fermentation, can be isolated by procedures well known in the art. A frequently-used procedure is to subject the harvested fermentation broth to separation techniques, e.g., centrifugation.

5 Example 2 — Cloning of Novel Toxin Genes from *B.t.* Isolate PS50C

10 Total cellular DNA was prepared from *Bacillus thuringiensis* (*B.t.*) cells grown to an optical density, at 600 nm, of 1.0. The cells were recovered by centrifugation and protoplasts were prepared in TES buffer (30 mM Tris-HCl, 10 mM EDTA, 50 mM NaCl, pH = 8.0) containing 20% sucrose and 50 mg/ml lysozyme. The
10 protoplasts were lysed by addition of SDS to a final concentration of 4%. The cellular material was precipitated overnight at 4°C in 100 mM (final concentration) neutral potassium chloride. The supernate was extracted twice with phenol/chloroform (1:1). Nucleic acids were precipitated with ethanol and DNA was purified by isopycnic banding on cesium chloride-ethidium bromide gradients.

15 Total cellular DNA from *B.t.* subsp. *kumamotoensis* (*B.t.kum.*), isolate PS50C, was digested with *Hind*III and fractionated by electrophoresis on a 0.8% (w/v) agarose-TAE (50 mM Tris-HCl, 20 mM NaOAc, 2.5 mM EDTA, pH = 8.0) buffered gel. A Southern blot of the gel was hybridized with a [³²P]-radiolabeled
20 oligonucleotide probe. Results showed that the hybridizing fragments of PS50C are approximately 12 Kb and 1.7 Kb in size.

25 A library was constructed from PS50C total cellular DNA partially digested with *Sau*3A and size fractionated by gel electrophoresis. The 9-23 Kb region of the gel was excised and the DNA was electroeluted and then concentrated using an Elutip-d™ ion exchange column (Schleicher and Schuel, Keene, NH). The isolated *Sau*3A
30 fragments were ligated into *Bam*HI-digested LambdaGEM-11™ (PROMEGA). The packaged phage were plated on *E. coli* KW251 cells (PROMEGA) at a high titer and screened using the radiolabeled oligonucleotide probe. Hybridizing plaques were purified and rescreened at a lower plaque density. Single isolated, purified plaques that hybridized with the probe were used to infect *E. coli* KW251 cells in liquid culture for preparation of phage for DNA isolation. DNA was isolated by standard procedures. Preparative amounts of DNA were digested with *Xho*I (to release the inserted DNA from lambda sequences) and separated by electrophoresis on a 0.6%

agarose-TAE gel. The large fragments were purified by ion exchange chromatography as above and ligated to *Xho*I-digested, dephosphorylated pHTBlueII (an *E. coli*/*B. thuringiensis* shuttle vector comprised of pBluescript s/k [Stratagene] and the replication origin from a resident *B.t.* plasmid [D. Lereclus *et al.* (1989) *FEMS Microbiology Letters* 60:211-218]). The ligation mix was introduced by transformation into competent *E. coli* NM522 cells (ATCC 47000) and plated on LB agar containing ampicillin, isopropyl-(β)-D-thiogalactoside (IPTG) and 5-bromo-4-chloro-4-indolyl-(β)-D-galactoside (XGAL). White colonies, with putative restriction fragment insertions in the (β)-galactosidase gene of pHTBlueII, were subjected to standard rapid plasmid purification procedures. Plasmids were analyzed by *Xho*I digestion and agarose gel electrophoresis. The desired plasmid construct, pMYC1638, contains an approximately 12 Kb *Xho*I insert. A partial restriction map of the cloned insert indicates that the toxin gene is novel compared to the maps of other toxin genes encoding insecticidal proteins. The nucleotide sequence (open reading frame only), which has been designated 50C(a) is shown in SEQ ID NO. 1. The predicted peptide sequence of the toxin is shown in SEQ ID NO. 2.

Plasmid pMYC1638 was introduced into an acrySTALLIFEROUS (Cry⁻) *B.t.* host (HD-1 cryB obtained from A. Aronson, Purdue University) by electroporation. Expression of an approximately 130 kDa protein was verified by SDS-PAGE.

Plasmid pMYC1638 containing the *B.t.* toxin gene, can be removed from the transformed host microbe by use of standard well-known procedures. For example, *E. coli* NM522[pMYC1638] NRRL B-18751 can be subjected to cleared lysate isopycnic density gradient procedures, and the like, to recover pMYC1638.

A second gene, designated 50C(b), has also been cloned and sequenced from PS50C. The nucleotide sequence for 50C(a) is shown in SEQ ID NO. 3, and the predicted amino acid sequence for this toxin is shown in SEQ ID NO. 4.

Example 3 — Cloning of Toxin Gene From *B.t.* Isolate PS43F and Transformation into *Pseudomonas*

Total cellular DNA was prepared by growing the cells of *B.t.* isolate PS43F and M-7 to a low optical density ($OD_{600} = 1.0$) and recovering the cells by centrifugation. The cells were protoplasted in a buffer containing 20% sucrose and

50 mg/ml lysozyme. The protoplasts were lysed by addition of SDS to a final concentration of 4%. The cellular material was precipitated overnight at 4°C in 100 mM neutral potassium chloride. The supernate was phenol/chloroform extracted twice and the DNA precipitated in 68% ethanol. The DNA was purified on a cesium chloride gradient. DNAs from strains 43F and M-7 (as a standard of reference) were digested with *Eco*RI and run out on a 0.8% agarose gel. The gel was Southern blotted and probed with the nick translated ORF *Xmn*I to *Pst*I fragment of the toxin encoding gene isolated from M-7 (this will be subsequently referred to as Probe). The results showed 43F to hybridize to Probe at 7.5 kb which is different than the standard.

Preparative amounts of 43F DNA were digested with *Eco*RI and run out on a 0.8% agarose gel. The 7.5 kb region of the preparative gel was isolated and the DNA electroeluted and concentrated using an ELUTIPTM-d (Schleicher and Schuell, Keene, NH) ion exchange column. A sample was blotted and probed to verify the fragment was indeed isolated. The 7.5 kb *Eco*RI fragment was ligated to Lambda ZAPTM *Eco*RI arms. The packaged recombinant phage were plated out with *E. coli* strain BB4 (Stratagene Cloning Systems, La Jolla, CA) to give high plaque density.

The plaques were screened by standard procedures with Probe. The plaques that hybridized were purified and re-screened at a lower plaque density. The resulting phage were grown with M13 helper phage (Stratagene) and the recombinant BLUESCRIPTTM plasmid was automatically excised and packaged. The "phagemid" was re-infected in XL1-blue *E. coli* cells (Stratagene) as part of the automatic excision process. The infected XL1-blue cells were screened for ampicillin resistance and the resulting colonies were miniprepmed to find the desired plasmid pM1,98-4. The recombinant *E. coli* XL1-Blue (pM1,98-4) strain is called MR381.

The plasmid pM1,98-4 contained a 7.5 kb *Eco*RI insert. To verify that this insert was the one of interest, a Southern blot was performed and probed. The 7.5 kb band hybridized with Probe, confirming that the fragment had been cloned. Restriction endonuclease analysis of the 7.5 kb *Eco*RI fragment with the enzymes *Hind*III, *Pst*I, *Spe*I, *Bam*HI and *Xba*I was done to show that a gene different from M-7 had been cloned. The enzymes which cut inside the 7.5 kb *Eco*RI fragment were *Hind*III (twice) *Spe*I (twice) and *Pst*I (once). The open reading frame (ORF) of the 43F gene cut once with *Hind*III, twice with *Spe*I and did not cut with *Xba*I, *Eco*RI,

or *Bam*HI. The nucleotide sequence for the 43F gene is shown in SEQ ID NO. 5 and the predicted amino acid sequence for this toxin is provided in SEQ ID NO. 6.

The cloned toxin gene from PS43F can be modified for expression in *P. fluorescens* in the following way:

5 (1) A plasmid containing the *Ptac*-promoted *cryIA(b)*-like toxin gene can be made using a 3-way ligation involving the *Ptac* promoter and toxin gene on a *Bam*HI-*Pst*I fragment of about 4500 bp from pM3,130-7 (from MR420, NRRL B-18332, disclosed in U.S. Patent No. 5,055,294), a *Not*I-*Bam*HI fragment of about 5500 bp from pTJS260 (containing the tetracycline resistance genes, available from Dr. Donald
10 Helinski, U.C. San Diego), and a *Not*I-*Pst*I fragment of about 6100 bp from pTJS260 (containing the replication region). The assembled plasmid is recovered following transformation of *E. coli* and growth under tetracycline selection.

(2) A plasmid containing the *Ptac*-promoted 43F toxin gene can be made by ligating the toxin gene-containing *Fsp*I-*Ssp*I fragment of about 2200 bp from pM1,98-4
15 (from MR381(pM1,98-4), NRRL B-18291) into the *Sma*I site of the *E. coli* vector, pKK223-3 (Pharmacia). The *Ptac*-promoted 43F toxin plasmid can be recovered following transformation of *E. coli*, growth under ampicillin selection, and screening for plasmids with inserts in the proper orientation for expression from the *tac* promoter by techniques well known in the art.

20 (3) The *Ptac*-promoted 43F toxin can be assembled into, for example, the pTJS260-derived vector in a three-way ligation using the 12.6 kb DNA fragment having *Bam*HI and filled-in *Nsi*I ends from the plasmid resulting from step 1 above, to the *Bam*HI-*Nsi*I *Ptac*-containing fragment of about 1.2 kb and the *Nsi*I-*Sca*I fragment of about 2.1 kb containing the 3Q end of the 43F toxin gene and adjacent
25 vector DNA from the plasmid resulting from step 2 above.

The resulting pTJS260-derived 43F toxin expression plasmid can be introduced into *Pseudomonas fluorescens* by electroporation.

The above cloning procedures were conducted using standard procedures unless otherwise noted.

30 The various methods employed in the preparation of the plasmids and transformation of host organisms are well known in the art. These procedures are described in Maniatis, T., E.F. Fritsch, J. Sambrook (1982) *Molecular Cloning: A*

Laboratory Manual, Cold Spring Harbor Laboratory, New York. Thus, it is within the skill of those in the genetic engineering art to extract DNA from microbial cells, perform restriction enzyme digestions, electrophorese DNA fragments, tail and anneal plasmid and insert DNA, ligate DNA, transform cells, prepare plasmid DNA, electrophorese proteins, and sequence DNA.

The restriction enzymes disclosed herein can be purchased from Boehringer Mannheim, Indianapolis, IN, or New England BioLabs, Beverly, MA. The enzymes were used according to the instructions provided by the supplier.

Plasmid pM1,98-4 containing the *B.t.* toxin gene, can be removed from the transformed host microbe by use of standard well-known procedures. For example, *E. coli* XL1-Blue (pM1,98-4) can be subjected to cleared lysate isopycnic density gradient procedures, and the like, to recover pM1,98-4.

Example 4 — Testing of *B.t.* PS86B1 and Transformed Hosts

Third instar Pasadena Masked Chafers, *Cyclocephala pasadenae*, were found to be susceptible to the *B.t.* isolate PS86B1 as well as a *Pseudomonas fluorescens* transformed host containing the δ -endotoxin expressing gene obtained from *B.t.* PS43F. In the bioassays, larvae were fed an aqueous suspension of the material mixed with ryegrass roots. Larvae were held with the treated diet at room temperature in 1 oz. plastic cups, and observed for mortality by prodding. Dosages of PS86B1 and the *Pseudomonas fluorescens* transformed host greater than 500 ppm (δ -endotoxin protein/diet) gave 80% control in 15 days.

Example 5 - Testing of *B.t.* Transformed Host Containing a δ -Endotoxin Gene from PS50C

The transformed host was prepared by introducing plasmid pMYC1638 (NRRL B-18751), containing the δ -endotoxin expressing gene obtained from *B.t.* PS50C, into an acrySTALLIFEROUS (cry⁻) *B.t.* host (HD-1 cryB obtained from A. Aronson, Purdue University) by standard electroporation procedures.

Larvae of *Cotinis* sp. were found to be susceptible to the transformed host containing the δ -endotoxin expressing gene obtained from the *B.t.* isolate PS50C. The larvae were fed an aqueous suspension of the transformed host mixed with peat moss.

The larvae were held at room temperature in 1 oz. plastic cups with the treated peat, and checked regularly during the assays for mortality. Dosages of the transformed host of 750 ppm (δ -endotoxin/diet) caused 90% mortality of the larvae by day 13. In addition, the transformed host was shown to affect all three instar stages of the larvae.

5

Example 6 - Testing of *B.t.* PS86B1 Against *Cyclocephala borealis*

Third instar Northern Masked Chafer *Cyclocephala borealis* were found to be susceptible to the *B.t.* isolate PS86B1. Larvae were fed Kentucky bluegrass roots which had been dipped in a *B.t.* suspension. Larvae were held at room temperature in 1 oz. cups containing the treated roots and observed for mortality by prodding. Dosages greater than 500 ppm (protein/diet) gave 79% control in 7 days.

10

Example 7 - Testing of *B.t.* PS86B1 Against *Popillia japonica*

Third instar Japanese beetle *Popillia japonica* were found to be susceptible to the *B.t.* isolate PS86B1. Larvae were fed a *B.t.* suspension mixed with compost. Larvae were held with the treated compost at room temperature in 1 oz. plastic cups and observed for mortality by prodding. Dosages of PS86B1 greater than 500 ppm (protein/diet) gave greater than 40% control in 7 days.

15

Example 8 - Insertion of Toxin Genes Into Plants

20

One aspect of the subject invention is the transformation of plants with genes encoding a scarab-active toxin. The transformed plants are resistant to attack by scarab pests.

25

Genes encoding scarab-active toxins, as disclosed herein, can be inserted into plant cells using a variety of techniques which are well known in the art. For example, a large number of cloning vectors comprising a replication system in *E. coli* and a marker that permits selection of the transformed cells are available for preparation for the insertion of foreign genes into higher plants. The vectors comprise, for example, pBR322, pUC series, M13mp series, pACYC184, etc. Accordingly, the sequence encoding the *B.t.* toxin can be inserted into the vector at a suitable restriction site. The resulting plasmid is used for transformation into *E. coli*. The *E. coli* cells are cultivated in a suitable nutrient medium, then harvested and lysed. The plasmid

30

is recovered. Sequence analysis, restriction analysis, electrophoresis, and other biochemical-molecular biological methods are generally carried out as methods of analysis. After each manipulation, the DNA sequence used can be cleaved and joined to the next DNA sequence. Each plasmid sequence can be cloned in the same or other plasmids. Depending on the method of inserting desired genes into the plant, other DNA sequences may be necessary. If, for example, the Ti or Ri plasmid is used for the transformation of the plant cell, then at least the right border, but often the right and the left border of the Ti or Ri plasmid T-DNA, has to be joined as the flanking region of the genes to be inserted.

The use of T-DNA for the transformation of plant cells has been intensively researched and sufficiently described in EP 120 516; Hoekema (1985) In: *The Binary Plant Vector System*, Offset-drukkerij Kanters B.V., Alblasterdam, Chapter 5; Fraley *et al.*, *Crit. Rev. Plant Sci.* 4:1-46; and An *et al.* (1985) *EMBO J.* 4:277-287.

Once the inserted DNA has been integrated in the genome, it is relatively stable there and, as a rule, does not come out again. It normally contains a selection marker that confers on the transformed plant cells resistance to a biocide or an antibiotic, such as kanamycin, G 418, bleomycin, hygromycin, or chloramphenicol, *inter alia*. The individually employed marker should accordingly permit the selection of transformed cells rather than cells that do not contain the inserted DNA.

A large number of techniques are available for inserting DNA into a plant host cell. Those techniques include transformation with T-DNA using *Agrobacterium tumefaciens* or *Agrobacterium rhizogenes* as transformation agent, fusion, injection, or electroporation as well as other possible methods. If agrobacteria are used for the transformation, the DNA to be inserted has to be cloned into special plasmids, namely either into an intermediate vector or into a binary vector. The intermediate vectors can be integrated into the Ti or Ri plasmid by homologous recombination owing to sequences that are homologous to sequences in the T-DNA. The Ti or Ri plasmid also comprises the *vir* region necessary for the transfer of the T-DNA. Intermediate vectors cannot replicate themselves in agrobacteria. The intermediate vector can be transferred into *Agrobacterium tumefaciens* by means of a helper plasmid (conjugation). Binary vectors can replicate themselves both in *E. coli* and in agrobacteria. They comprise a selection marker gene and a linker or polylinker which

are framed by the right and left T-DNA border regions. They can be transformed directly into agrobacteria (Holsters *et al.* [1978] *Mol. Gen. Genet.* 163:181-187). The agrobacterium used as host cell is to comprise a plasmid carrying a *vir* region. The *vir* region is necessary for the transfer of the T-DNA into the plant cell. Additional
5 T-DNA may be contained. The bacterium so transformed is used for the transformation of plant cells. Plant explants can advantageously be cultivated with *Agrobacterium tumefaciens* or *Agrobacterium rhizogenes* for the transfer of the DNA into the plant cell. Whole plants can then be regenerated from the infected plant material (for example, pieces of leaf, segments of stalk, roots, but also protoplasts or
10 suspension-cultivated cells) in a suitable medium, which may contain antibiotics or biocides for selection. The plants so obtained can then be tested for the presence of the inserted DNA. No special demands are made of the plasmids in the case of injection and electroporation. It is possible to use ordinary plasmids, such as, for example, pUC derivatives.

15 The transformed cells grow inside the plants in the usual manner. They can form germ cells and transmit the transformed trait(s) to progeny plants. Such plants can be grown in the normal manner and crossed with plants that have the same transformed hereditary factors or other hereditary factors. The resulting hybrid individuals have the corresponding phenotypic properties.

20 Example 9 — Cloning of Novel *B.t.* Genes Into Insect Viruses

A number of viruses are known to infect insects. These viruses include, for example, baculoviruses and entomopoxviruses. In one embodiment of the subject invention, lepidopteran-active genes, as described herein, can be placed with the
25 genome of the insect virus, thus enhancing the pathogenicity of the virus. Methods for constructing insect viruses which comprise *B.t.* toxin genes are well known and readily practiced by those skilled in the art. These procedures are described, for example, in Merryweather *et al.* (Merryweather, A.T., U. Weyer, M.P.G. Harris, M. Hirst, T. Booth, R.D. Possee [1990] *J. Gen. Virol.* 71:1535-1544) and Martens *et al.*
30 (Martens, J.W.M., G. Honee, D. Zuidema, J.W.M. van Lent, B. Visser, J.M. Vlak [1990] *Appl. Environmental Microbiol.* 56(9):2764-2770).

It should be understood that the examples and embodiments described herein are for illustrative purposes only and that various modifications or changes in light thereof will be suggested to persons skilled in the art and are to be included within the spirit and purview of this application and the scope of the appended claims.

Claims

1. A method for controlling scarab pests which comprises contacting said pests with a scarab-controlling effective amount of a *Bacillus thuringiensis* strain or toxin selected from the group consisting of *Bacillus thuringiensis* PS86B1, *Bacillus thuringiensis* PS43F, *Bacillus thuringiensis* PS50C, toxins of said microbes, and variants of said microbes and toxins which have activity against scarabs.

2. The method, according to claim 1, wherein said *Bacillus thuringiensis* is *Bacillus thuringiensis* PS86B1.

3. The method, according to claim 1, wherein said *Bacillus thuringiensis* is *Bacillus thuringiensis* PS43F.

4. The method, according to claim 1, wherein said *Bacillus thuringiensis* is *Bacillus thuringiensis* PS50C.

5. A composition of matter for controlling scarab pests comprising a *Bacillus thuringiensis* strain or toxin selected from the group consisting of *Bacillus thuringiensis* PS86B1, *Bacillus thuringiensis* PS43F, *Bacillus thuringiensis* PS50C, toxins of said microbes, and variants of said microbes and toxins which have activity against scarabs, in association with an inert carrier.

6. A method for controlling scarab pests which comprises contacting said scarab pests with a scarab-controlling amount of a pesticidal composition comprising intact treated cells having prolonged pesticidal activity when applied to the environment of scarab larvae, wherein said insecticide is produced by a gene which encodes a toxin selected from the group consisting of toxins expressed by a *Bacillus thuringiensis* selected from the group consisting of *Bacillus thuringiensis* PS86B1, *Bacillus thuringiensis* PS43F, *Bacillus thuringiensis* PS50C, and toxins which are variants of the toxins expressed by said microbes and which have activity against scarabs.

7. A polynucleotide sequence comprising DNA wherein said DNA encodes a toxin which is active against scarab pests and wherein said DNA, or a variant thereof, is obtainable from a *Bacillus thuringiensis* strain selected from the group consisting of *Bacillus thuringiensis* PS86B1, *Bacillus thuringiensis* PS43F, *Bacillus thuringiensis* PS50C, and variants of said microbes which have activity against scarabs.

8. The polynucleotide sequence, according to claim 7, comprising DNA encoding all or part of SEQ ID NO. 2.

9. The polynucleotide sequence, according to claim 8, comprising DNA having all or part of SEQ ID NO. 1.

10. The polynucleotide sequence, according to claim 7, comprising DNA encoding all or part of SEQ ID NO. 4.

11. The polynucleotide sequence, according to claim 10, comprising DNA having all or part of SEQ ID NO. 3.

12. The polynucleotide sequence, according to claim 7, comprising DNA encoding all or part of SEQ ID NO. 6.

13. The polynucleotide sequence, according to claim 12, comprising DNA having all or part of SEQ ID NO. 5.

14. A toxin which is active against scarab pests and which is encoded by a polynucleotide sequence of claim 7.

15. The toxin, according to claim 14, having all or part of SEQ ID NO. 2.

16. The toxin, according to claim 14, having all or part of SEQ ID NO. 4.

17. The toxin, according to claim 14, having all or part of SEQ ID NO. 6.
18. A plant cell transformed by a polynucleotide sequence of claim 7.
19. A microbe transformed by a polynucleotide sequence of claim 7.

(54) Title: PROCESS FOR CONTROLLING SCARAB PESTS WITH <i>BACILLUS THURINGIENSIS</i> ISOLATES (57) Abstract Certain isolates of <i>Bacillus thuringiensis</i> (B.t.) have been found to have activity against scarab pests. These isolates are designated B.t. PS86B1, B.t. PS43F and B.t. PS50C. These isolates, or transformed hosts containing the gene expressing a scarab-active toxin obtained from the isolates, can be used to control scarab-active pests, e.g., masked chafer, <i>Cyclocephala</i> sp., June beetle, <i>Cotinis</i> sp., northern masked chafer, <i>Cyclocephala borealis</i> , Japanese beetle, <i>Popillia japonica</i> , and Pasadena masked chafer, <i>Cyclocephala pasadenae</i> , in various environments.

III. DOCUMENTS CONSIDERED TO BE RELEVANT⁹

Category ¹⁰	Citation of Document, ¹¹ with indication, where appropriate, of the relevant passages ¹²	Relevant to Claim No. ¹³
X	EP,A,0330342 (MYCOGEN CORPORATION) 30 August 1989	1-2,5-6
Y	see the whole document	7,14,18 -19
Y	--- MICROBIOLOGICAL REVIEWS vol. 53, no. 2, June 1989, WASHINGTON DC, US pages 242 - 255 H\FTE, H. & WHITELEY, H.R. 'Insecticidal crystal proteins of Bacillus thuringiensis' see the whole document --- -/-	7,14,18 -19

¹⁰ Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

III. DOCUMENTS CONSIDERED TO BE RELEVANT (CONTINUED FROM THE SECOND SHEET)

Category *	Citation of Document, with indication, where appropriate, of the relevant passages	Relevant to Claim No.
A	JOURNAL OF INVERTEBRATE PATHOLOGY vol. 27, no. 3, May 1976, NEW YORK, US pages 421 - 422 SHARPE, E.S. 'Toxicity of the parasporal crystal of Bacillus thuringiensis to japanese beetle larvae' see the whole document ---	1,6
A	LETTERS IN APPLIED MICROBIOLOGY vol. 14, no. 2, 29 January 1992, OXFORD, GB pages 54 - 57 OHBA, M. ET AL. 'A unique isolate of Bacillus thuringiensis serovar japonensis with high larvicidal activity specific for scarabaeid beetles' see the whole document ---	1,6
A	THE MADRAS AGRICULTURAL JOURNAL vol. 58, 1971, pages 114 - 116 SHINDE, V. & SHARMA, S. 'Bacteria pathogenic to Lachnosterna consanguinea Blanch (Coleoptera:Scarabaeidae)' see the whole document -----	1,6

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 93/00966

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see PCT/ISA/206 mailed on 15.09.93

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☒ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

1, 5-7, 14, 18-19 (partially); 2 completely

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
